

# Scope of Microtechniques

---

Muhammad Zubair Hassan

Microtechniques

# Overview of the lecture

---

- Introduction to Microtechniques
- Scope of Microtechniques
- Tissue Processing
- Cytological Preparation
- IHC and Special Stains
- Molecular Pathology

# ...Continued

---

- Microscopic Examination
- Quality Control and Research

# Introduction to Microtechniques

---

- Microtechniques = small lab methods used in pathology
- Help to prepare and study tissues, cells, and body fluids
- Important for diagnosis, research, and teaching
- Help us understand diseases better

# Tissue Processing

---

- Used to handle tissue samples from surgery, biopsy, or autopsy
- Main steps:
- **Fixation** → preserves tissue
- **Embedding** → keeps tissue firm for cutting
- **Sectioning** → cutting thin slices
- **Staining & Mounting** → adding color and placing on slides for study

# Fixation

How much Formalin do I need ?

1:20  
by volume!

Yes, 20 times more formalin than your sample! Your sample should also be free to drift with lots of space around it.

Too little formalin! Squished to the sides! Too little formalin!

Even if your tissue can fit in the container, it needs a lot more formalin and space! Eppendorf and PCR tubes are too small! If it is even slightly squished, it might not fix well!

The diagram illustrates the correct and incorrect ways to fix tissue. It shows three correct examples in a green box: a petri dish with tissue submerged in formalin, a test tube with tissue submerged, and a petri dish with tissue submerged. Below these, it shows three incorrect examples in a red box, each crossed out with a red X: a small vial with tissue at the bottom, a test tube with tissue pressed against the side, and a petri dish with tissue pressed against the side. The text emphasizes that the sample should be free to drift in the formalin and that small containers like Eppendorf and PCR tubes are not suitable for fixation.

Drive wheel  
Block holder  
Paraffin block  
Tissue  
Steel knife

# Cytological Preparation

---

- **Cytology** → Study of single cells
- Examples: Pap smears, fluid samples, FNAs (needle samples)
- Helps to detect cancer and infections
- **Special Stains & IHC**
- Show proteins, antigens, and cell structures
- Help doctors confirm diseases

# Molecular Pathology

---

- Focuses on **DNA** and **RNA** (genetic material)
- Common methods:
- **PCR** (copying DNA)
- **FISH** (seeing genes with fluorescent colors)
- **Immunofluorescence** (using glowing antibodies)
- Useful for detecting genetic and infectious diseases

# Microscopic Examination

---

- Uses different microscopes to look at tissues and cells:
  - Light microscope
  - Fluorescent microscope
  - Electron microscope
  - Digital imaging systems
- Helps to see cell details, abnormalities, and disease signs

# Quality Control & Research

---

- Making sure lab work is correct and reliable
- Includes:
  - Maintaining equipment
  - Improving lab methods
  - Checking test accuracy
  - Doing experiments for better results

# Next Lecture

---

- Relationship with other branches of pathology
- Branches of pathology enhanced by Microtechniques

Any Questions?

THANK  
YOU
